ᄩ	Ĺĺ	/ɫ/			
ᄭ	Xx	/χ~x/			
ᄮ	Ww	/w/			
ᄯ	Yy	/j/			

Additional Notes on Ámro Phonology & Orthography

As in many modern human languages, Ámro has certain phonemes that only occur as digraphs. You may have noticed how /c/ and /ɟ/ are listed as distinct phonemes in the table but do not have their own letters; this is because /c/ results from the digraph *ky* $\widehat{\Psi}$, and /ɟ/ results from the digraphs *gy* $\widehat{\Psi}$ and *dy* $\succ\Psi$.

The phoneme / ϕ / occurs under two circumstances: either in place of /p/ occurring before unstressed vowels or before /i/, or in place of /w/ occurring before stressed vowels, in this case pronounced as [$\phi\widehat{w}$]. While the phoneme was never distinguished from letters $\mathcal{C}$ or $\mathcal{Q}$ in Cécamro, ASR clarified these rules by introducing the digraph *ph*, used to denote / ϕ / wherever it occurs.

The phoneme / χ / is generally pronounced as the allophone /x/ before the phonemes /ɪ/ or /i/.

All vowels become nasalized when they occur before a nasal consonant, and for syllables ending in /m/, the /m/ is not pronounced resulting in a pure nasal consonant - for example, "Kamám" is pronounced [kə'mã].

The phonemes /b/ and /g/ are sometimes pronounced as /β/ and /ɣ/ respectively when occurring between vowels. However, this is not a concrete pronunciation rule and the use of /b/ and /g/ exclusively can still be understood.
